**Progressive climate change is resulting** in a greater frequency and severity of hypoxic environments. This influences all aquatic organisms. To investigate the potential impacts and capacity for local adaptation, our model species was one of the most iconic fishes in tropical Australia: the barramundi.

Intermittent flow-through respirometry was used to measure oxygen consumption ( $\dot{MO}_{2}$ )

**OXYGEN CONSUMPTION** , kg <sup>1</sup> min <sup>1</sup> 3.0 <sup>1</sup> 3.0 MO2 Rest = 1.8 mg O2 kg<sup>-1</sup> mir ő (mg

The critical oxygen tension ([O<sub>2</sub>]<sub>crit</sub>: the point at which an animal is no longer able to regulate  $O_2$ consumption independent of the surrounding environment) was used as an indicator of hypoxia tolerance

**Hypoxia** = low dissolved oxygen

# **RESEARCH QUESTIONS**

**1. How tolerant are barramundi of** environmental hypoxia?

- **2.** Does hypoxia tolerance change with temperature?
- **3. Does hypoxia tolerance differ between sub-populations?**

**GENETICALLY DISTINCT SUB-POPULATIONS** 

![](_page_0_Figure_22.jpeg)

**1. All barramundi can regulate their** MO<sub>2</sub> down to ~ 30 % saturation and can be considered highly tolerant of hypoxia

![](_page_0_Figure_24.jpeg)

### **RESTING OXYGEN CONSUMPTION**

![](_page_0_Figure_26.jpeg)

2. Barramundi remain tolerant of environmental hypoxia at higher temperatures

3. We were unable to find conclusive evidence for differences in hypoxia tolerance between different subpopulations

## **OUTCOMES AND IMPLICATIONS**

Barramundi have evolved in environments with variable temperature, rainfall and dissolved O<sub>2</sub> and thus may be resilient to global climate change

![](_page_0_Figure_31.jpeg)

Map of Australia, depicting locations of genetically distinct subpopulations of barramundi used in this study. Boxplots on the right depict the mean temperature and variation in temperature at three locations across the species distribution, with temperatures at low (equatorial) latitudes characterised by a higher mean and lower variability.

Barramundi consumer **twice** as much O<sub>2</sub> at 36°C than at 26°C ( $Q_{10} = 2.1 \pm 0.3$ )
